What is Addiction?

• commonly associated with a chronic, relapsing course

• Drug addiction is a chronically relapsing disorder that has been characterized by
  – (1) compulsion to seek and take the drug,
  – (2) loss of control in limiting intake, and
  – (3) emergence of a negative emotional state (e.g., dysphoria, anxiety, irritability) reflecting a motivational withdrawal syndrome when access to the drug is prevented.
How Common is Addiction?

• **Alcohol**: 17 million Americans (11% of the population) are addicted (steady for the past few decades)

• **Nicotine**: 55 million Americans (21% of the population) are addicted (decreasing... For now... E-cigarettes may change this)

• **CANNABIS**: ~9 million (6% of the population) Americans are addicted (increasing - *increases occurred across gender, region, educational level, and employment status*)

• **VAPING**: nicotine or cannabis or both: 37 percent of 12th graders report vaping (dramatic increase- nearly **doubling**)

• **5.4 million** (3% of the population): addiction to **illicit drugs/non-prescribed drugs** (*increasing* due to opiates)
Drug overdose is now the leading cause of accidental death in the U.S.

The death toll has doubled in the last decade, now claiming a life every 14 minutes, making it the number one cause of preventable deaths.
Addiction is Like Other Diseases...

➢ It is preventable
➢ It is treatable
➢ It changes biology
➢ If untreated, it can last a lifetime

Advances in science have revolutionized our fundamental views of drug abuse and addiction.
Your Brain on Drugs in the 1980’s

this is your brain on drugs.
Today’s Talk

• **Who gets Addicted?**
• The Addiction Cycle
  – Role of Dopamine/Reward in Addiction
  – Role of Impaired Inhibition in Addiction
• Changes in the Brain that Occur
• Treatment and Recovery
Why do some people become addicted to drugs while others do not?
Individual Variability

• Inhibitory control abnormalities? Reward Responsiveness? Stress sensitivity? Resilience?
• Mood, anxiety, psychotic disorders are clear risk factors
• 40-60% of the risk for addiction attributed to genetic factors.
Who is Predisposed to Addiction?

• The Marshmallow Test: Behavioral and Neural Correlates of Ability to Delay Gratification: 40 Years Later

• 4 year-olds who were able to resist eating one marshmallow in exchange for two marshmallows 15 minutes later showed lower rates of substance use 40 years later.
Addiction is a Developmental Disease that starts in adolescence and childhood.

Age at tobacco, alcohol, and cannabis dependence per DSM IV.
Why do Mental Illnesses and Substance Abuse Co-occur?

• **Self-medication**
  – substance abuse begins as an attempt to alleviate symptoms of mental illness

• **Causal effects**
  – Substance abuse may increase vulnerability to mental illness

• **Common or correlated causes**
  – the risk factors that give rise to mental illness and substance abuse may be related or overlap
Addictiveness by Drug Type

Cannabis in the 1960’s-2000’s: THC 1-3%
Marijuana is not “just a plant” anymore – derivatives contain up to 98% THC
Borodovsky et al., 2016; Schauer, King et al., 2016; Wang et al., 2016; Weiss, 2015
Marijuana growers have worked to make the drug as potent as possible.

- In 1960s-70s average THC concentrations were 1-2%. Today, they are as high as 25%
High Potency Marijuana may lead to psychosis

In Amsterdam, half of all new cases of psychosis were linked with high potency use

Figure 2: Fully adjusted ORs of psychotic disorders for the combined measure of frequency plus type of cannabis use in three sites. Data are shown for the three sites with the greatest consumption of cannabis: London (201 cases, 230 controls), Amsterdam (96 cases, 101 controls), and Paris (54 cases, 100 controls). Error bars represent 95% CIs. OR=odds ratio.
Fig. 1. Mortality rates from unintentional drug overdoses. (A and B) Mortality rates for (A) individual drugs and (B) all drugs. Detailed data for individual drugs are only available from 1999 to 2016, although additional data for all drugs are available since 1979 (this area is grayed out). The exponential equation and fit are shown for all drugs. (Synth Opioids OTM: synthetic opioids other than methadone. This category includes fentanyl and its analogs.)

Mortality rate in year $y$:

$$10^{-0.036 + 0.032 \times (y-1978)}$$

$R^2 = 0.99$
The Opioid Epidemic

SOURCES: Jalal et al., Science 361, 2018
TYPES OF OPIOID OVERDOSES

Drugs Involved in U.S. Overdose Deaths, 1999 to 2017

- Synthetic Opioids other than Methadone, 29,406
- Heroin, 15,958
- Natural and semi-synthetic opioids, 14,958
- Cocaine, 14,556
- Methamphetamine, 10,721
- Methadone, 3,295
WHAT ABOUT THOSE WITH ‘LEGITIMATE’ PRESCRIPTIONS?

FIGURE 1. One- and 3-year probabilities of continued opioid use among opioid-naïve patients, by number of days' supply* of the first opioid prescription — United States, 2006–2015

* Days’ supply of the first prescription is expressed in days (1–40) in 1-day increments. If a patient had multiple prescriptions on the first day, the prescription with the longest days’ supply was considered the first prescription.

Reward: stimulus that induces subjective feelings of pleasure.

Rewarding stimuli activate the mesocorticolimbic reward circuit.

All drugs of abuse share the ability to activate the this circuit.

- increase extracellular dopamine (DA) levels in the NAc

Di Chiara and Imperato, PNAS, 1988
Reward

- Enhanced dopamine in the NA is responsible for acute high or initial reinforcing effects of drugs of abuse.

- Drugs of abuse are able to more rapidly and markedly elevate DA levels to supraphysiological levels for sustained periods of time compared with natural rewards.

- Drugs outcompete natural reinforcers and end up “hijacking” and corrupting the initial process of reward processing.

Roberts & Koob, 1980
Is this Responsible for Addiction?

- Behaviors persist despite **tolerance** to the positive effects of drugs over time.
- Individuals maintain use of substances through negative reinforcement to **avoid negative states** such as withdrawal states or to attempt to self-medicate for underlying psychic distress.
- Degree of euphoria of a substance does not necessarily predict its addictiveness (i.e. nicotine).

(Berridge et al., 2009)
The Switch from Reward to Negative Reinforcement/Withdrawal

- Enhanced dopamine in the NA is responsible for acute high or initial reinforcing effects (i.e., positive reinforcement) of drugs of abuse.
- All major drugs of abuse activate the brain stress systems
  - Elevated corticotrophin releasing factor (CRF) in the amygdala

George, Le Moal, and Koob, 2012
Executive Function Component

- loss of control, impulsivity, and impaired decision-making capacity
- Involves:
  - Orbitofrontal cortex (OFC): assigns a motivational value based on a prediction of reward
  - Anterior cingulate (ACC): role in inhibitory control of behaviors
Abnormal Activity in Two Brain Systems:

1) **Reward** (drive to meet goals) – Strong urge to use drugs over natural rewards, associated with impulsivity

2) **Inhibition** (control of goal-directed behavior) – Reduced control over behavior despite negative consequences

~Both abnormalities are worsened by stress

Baler & Volkow, 2006; Koob & Volkow 2009
Inhibition: Just Say No?

• Addiction: loss of control over intense urges despite adverse consequences.

The model is:

Greater reinforcing (rewarding) properties of drugs/diminished reinforcement from natural rewards = greater drive to use drugs

Diminished inhibitory control over behavior as evidenced by reduced prefrontal cortical activity during decision-making tasks = greater use of drugs despite serious negative consequences
Just Say No??

• Addiction: loss of control over intense urges despite adverse consequences.

The model is:

Greater reinforcing (rewarding) properties of drugs/diminished reinforcement from natural rewards = greater drive to use drugs

Diminished inhibitory control over behavior as evidenced by reduced prefrontal cortical activity during decision-making tasks = greater use of drugs despite serious negative consequences

Substance use is particularly damaging to the adolescent brain

- high amounts of alcohol/cannabis exposure during adolescence:
  - disrupts processes of brain maturation
  - worsens neurocognitive functioning.

Science Has Generated Much Evidence Showing That...

Prolonged Drug Use Changes the Brain In Fundamental and Long-Lasting Ways
These changes are long-lasting
Morphine-induced CPP: Movement patterns during a 15-min test before and after four pairings of the left compartment with morphine 10 mg/kg, s.c.

German & Fields, 2006
Morphine CPP: Persistence of effect of drug-paired cues infrequent 15-min tests: no drug since training

Note the lack of extinction when test are widely spaced

Mueller et al., 2000
Who Gets Treatment??

8.3% of Americans have diabetes
Any diabetes treatment  84%
No treatment  16%
9.5% of Americans have a mood disorder in a given year
Any MH treatment  41%

No treatment  59%
7.4% of Americans have a substance use disorder in a given year
Any addiction treatment 9%
No treatment 91%
WHY?? People can’t afford treatment

How People Pay for Treatment

- 48.4% Own savings and earnings
- 34.8% Private health insurance
- 26.7% Medicaid
- 26.1% Public assistance other than Medicaid
- 19.2% Medicare
- 15.9% Funds from family members

[note: individuals could report multiple sources of funding for treatment]
WHY?? Not enough doctors! (ex: Suboxone)

Train more psychiatrists?
- <1% are current prescribers
- Many psychiatric clinics will not prescribe buprenorphine

Train more PCPs?
- <0.01% are prescribers
- Majority of primary care clinics will not prescribe buprenorphine

Train more addiction psychiatrists?
- About 20-40 new board-certified addiction psychiatrists per year in the US
Addiction is Similar to Other Chronic Illnesses Because:

- It has biological and behavioral components, both of which must be addressed during treatment.
- Recovery from it—protracted abstinence and restored functioning—is often a long-term process requiring repeated episodes of treatment.
- Relapses can occur during or after treatment, and signal a need for treatment adjustment or reinstatement.
- Participation in support programs during and following treatment can be helpful in sustaining long-term recovery.
Full recovery is a challenge but it is possible …
Conclusions

• Addiction is a brain disease, with both biological and behavioral risk factors
• Addiction consists of specific stages, that each involve different brain regions and different neurotransmitters
• Addiction disrupts brain circuits involved in judgment and decision-making, so that “saying no” becomes very difficult
• These disruptions of brain circuitry are long-lasting
• Specific treatments of addiction exist, and those treatments work to help patients maintain abstinence

• Thank you for your attention!!!
